

# 16-Bit, 4-Channel, CCD/CMOS Sensor Analog Front-End with Timing Generator

Check for Samples: VSP5610, VSP5611, VSP5612

# FEATURES

- Four-Channel CCD/CMOS Signal: 2-Channel, 3-Channel, and 4-Channel Selectable
- Power Supply: 3.3 V Only, Typ (Built-in LDO, 3.3 V to 1.8 V)
- Maximum Conversion Rate:
  - VSP5610: 35 MSPS
  - VSP5611: 50 MSPS
  - VSP5612: 70 MSPS
- **16-Bit Resolution**
- **CDS/SH Selectable**
- Maximum Input Signal Range: 2.0 V
- Analog and Digital Hybrid Gain:
  - Analog Gain: 0.5 V/V to 3.5 V/V in 3/64-V/V Steps
  - Digital Gain: 1 V/V to 2 V/V in 1/256-V/V Steps
- Offset Correction DAC: ±250 mV, 8-Bit
- Standard LVDS/CMOS Selectable Output:
  - LVDS:
    - Data Channel: 2-Channel, 3-Channel
    - Clock Channel: 1-Channel
    - 8-Bit/7-Bit Serializer Selectable
  - CMOS: 4 Bits × 4, 8 Bits × 2
- **Timing Generator:** 
  - Fast Transfer Clock: Eight Signals
  - Slow Transfer Clock: Six Signals
- Timing Adjustment Resolution: t<sub>MCLK</sub>/48
- Input Clamp/Input Reference Level Internal/External Selectable
- Reference DAC: 0.5 V, 1.1 V, 1.5 V, 2 V
- SPI<sup>™</sup>: Three-Wire Serial
- **GPIO: Four-Port**

# APPLICATIONS

- Copiers •
- **Facsimile Machines**
- **Scanners**

# DESCRIPTION

VSP5610/11/12 The are high-speed, high-performance, 16-bit analog-to-digital-converters (ADCs) that have four independent sampling circuit channels for multi-output charge-coupled device (CCD) and complementary metal oxide semiconductor (CMOS) line sensors. Pixel data from the sensor are sampled by the sample/hold (SH) or correlated double sampler (CDS) circuit, and are then converted to digital data by an ADC. Data output is selectable in low-voltage differential signaling (LVDS) or CMOS modes.

The VSP5610/11/12 include a programmable gain to support the pixel level inflection caused by luminance. The integrated digital-to-analog-converter (DAC) can be used to adjust the offset level for the analog input signal. Furthermore, the timing generator (TG) is integrated in these devices for the control of sensor operation.

The VSP5610/11/12 use 1.65 V to 1.95 V for the core voltage and 3.0 V to 3.6 V for I/Os. The core voltage is supplied by a built-in low-dropout regulator (LDO).

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet. SPI is a trademark of Motorola.

www.ti.com

This integrated circuit can be damaged by ESD. Texas Instruments recommends that all integrated circuits be handled with appropriate precautions. Failure to observe proper handling and installation procedures can cause damage.

ESD damage can range from subtle performance degradation to complete device failure. Precision integrated circuits may be more susceptible to damage because very small parametric changes could cause the device not to meet its published specifications.

(1) Stresses beyond those listed under absolute maximum ratings may cause permanent damage to the device. These are stress ratings only and functional operation of the device at these or any other conditions beyond those indicated under recommended operating conditions is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.

### PARAMETERIC MEASUREMENT INFORMATION

# Analog Input Specification (AIN1, AIN2, AIN3, AIN4)

The analog input specification has two signal inputs: negative and positive. These inputs are shown in Figure 1a and Figure 1b, respectively.

Figure 1. Analog Input Definition

| PARAMETER                       |                     | TEST CONDITIONS  | MIN                  | TYP   | TYP MAX | UNIT   |

# FUNCTIONAL BLOCK DIAGRAM

Figure 3. VSP5610/11/12 Block Diagram

# SYSTEM OVERVIEW

### INTRODUCTION

The VSP5610/11/12 are analog front-end (AFE) devices for CCD and CMOS line image sensor applications such as copiers, facsimile machines, etc. The VSP5610/11/12 each provide four independent data processing channels.

The data from each image sensor channel are sampled and held by either the SH or CDS circuit and are then converted into digital data by an ADC. The digital data for each channel are later converted into serial data that can be output in either LVDS mode or CMOS mode.

# AFE BLOCK

### ANALOG SIGNAL INPUT

These devices have four channels that can be used as analog input ports for an image sensor. In addition to the four-channel input, this AFE device also supports three-channel and two-channel inputs. Table 2 shows the register settings required to select the different channel modes.

| MODE          | AIN_CH_SEL | AIN1   | AIN2    | AIN3   | AIN4    |
|---------------|------------|--------|---------|--------|---------|
| Two-channel   | 2          | Active | Standby | Active | Standby |
| Three-channel | 1          | Active | Active  | Active | Standby |
| Four-channel  | 0          | Active | Active  | Active | Active  |

#### Table 2. Analog Input Channel Mode Selection

Each analog input supports CDS and simple SH circuits to accommodate CCD and CMOS image sensors. The sampling mode can be selected independently for each channel by configuring the internal registers. As shown in Table 3, if AINx\_SH\_CDS is set to '0', then the corresponding channel operates in CDS mode.

### Table 3. CDS/SH Mode Selection

| AINx_SH_CDS <sup>(1)</sup> | SH/CDS |
|----------------------------|--------|
| 0                          | CDS    |
| 1                          | SH     |

(1)  $AINx_POL = Analog input polarity setting register (x = 1, 2, 3, and 4).$ 

In addition, these devices also support independent selection of the input signal polarity for each channel. Input signal polarity can be set using the AINx\_POL register, where x = 1, 2, 3, or 4. The input signal range and polarity are defined in the *Analog Input Specification* section.

### Correlated Double Sampler (CDS) Mode (AINx\_SH\_CDS = 0)

CDS mode is designed to accommodate inputs from the CCD sensor. The output signal of a CCD image sensor is sampled twice during one pixel period. First, the reference interval is sampled by the SHP pulse, then the data interval is sampled by the SHD pulse. Subtracting these two samples provides the video information of the pixel as well as removes any noise common to both intervals. Thus, CDS plays an important role in reducing the reset noise and other low-frequency noises that are present on the CCD output signal. Figure 4 shows a diagram of CDS mode.

Figure 4. CDS Mode Input Circuit for CCD Signal

### Sample Hold (SH) Mode (AINx\_SH\_CDS = 1)

SH mode supports CCD and CMOS sensors. For the CCD sensor, the sensor signal pedestal level is clamped to the  $V_{CLP}$  level using an internal clamp circuit. SH samples only once during a pixel period. The SHD pulse is used to sample the CCD signal data interval. After sampling, the SH circuit takes the difference of the data and  $V_{CLP}$  levels to extract the video information.

For the CMOS input, the input clamp function should be set according to the requirements. If the sensor output is within the allowable input range, an ac-coupling capacitor for analog input may not be needed. When the sensor signal is directly input to the AFE, the SH circuit requires a reference voltage to set the black level. To use  $V_{CLP}$  as a reference, SH\_REFx\_EN should be enabled and AINGNDx then opened or coupled to GND with a capacitor. To use an external reference, it can be input to AINGNDx with sensor signals connected to AINx. Figure 5 shows a diagram of the SH mode.

(1) Under some conditions, the sensor signal can be directly input to the AFE without requiring an external capacitor.

(2) In SH mode, the SHP clock should be programmed so that it does not overlap the SHD clock.

### Figure 5. SH Mode Input Circuit for CCD or CMOS Signal

## INPUT CLAMP AND SENSOR REFERENCE

The CCD output signal has a large dc offset that may exceed the input range of the AFE input circuit. Therefore, this output signal is ac-coupled to the AFE through a capacitor, and the internal dc level is set to the clamp voltage ( $V_{CLP}$ ) by an internal clamp circuit. The VSP5610/11/12 provide three modes for clamp operation: pixel clamp, line clamp, and not clamped. These modes are shown in Table 4. The clamp mode can be set independently for each channel by configuring the AINx\_CLP\_SEL register.

| Table 4. Clamp | Mode Selection |
|----------------|----------------|
|----------------|----------------|

|             | MODE SETTING                | CLAMP ACTIVE CONDITION AND SETTING |                      |                                   |           |  |
|-------------|-----------------------------|------------------------------------|----------------------|-----------------------------------|-----------|--|
| CLAMP MODE  | AINx_CLP_SEL <sup>(1)</sup> | CDS/SH                             | CLP_y <sup>(2)</sup> | CLPDM AND<br>SHP_y <sup>(2)</sup> | SH_REF_EN |  |
| Pixel clamp | 0 (default)                 | CDS/SH                             | Active               | Active                            | Off       |  |
| Line clamp  | 1                           | CDS/SH                             | —                    | Active                            | Off       |  |
|             | 2                           | Only SH                            | —                    | —                                 | On        |  |
| Not clamped | 3                           | Only SH                            | _                    | —                                 | Off       |  |

(1) AINx\_CLP\_SEL (x = 1, 2, 3, and 4).

(2) y = A and B.

In pixel clamp mode, CLP\_A/B is used for clamping. The input signal is clamped to  $V_{CLP}$  via the CLP\_A/B pulse during each pixel period, as shown in Figure 6a. Because the ac-coupling capacitor is charged on a pixel-to-pixel basis, the clamp level droop can be controlled by the clamp pulse width.

In line clamp mode, SHP\_A/B is used for clamping when CLPDM is active, as shown in Figure 6b. The input signal is clamped only in the CLPDM period within one line cycle of the sensor. The signal is clamped in this method because the charge leaks the least from the coupling capacitor during the CLPDM period. Accordingly, because there may be a large droop in the clamp level, this device does not support line clamp in the SH mode.

The *not-clamped* mode is mainly used in for a CMOS sensor input. If the sensor signal is directly connected to the AFE, this mode should be configured without an ac-coupling capacitor at the input port. This mode has two options to select a reference for the sensor black level: internal reference and external input. In the internal reference option, the internal reference ( $V_{CLP}$ ) is used with AINx\_CLP\_SEL = 2. In the external input option, the external input is used from AINGNDx with AINx\_CLP\_SEL = 3.

(1) x = AIN channel number, x = 1, 2, 3, and 4.

(2) y = Group code of sample pulse signals. When x = 1 or 2, y = A. When x = 3 or 4, y = B.

Figure 6. Input Clamp Function

As shown in Figure 7, the internal  $V_{CLP}$  node provides the clamp reference voltage. As for the clamp level, it is possible to select three reference voltage modes by setting the AINx\_REF\_SEL register. The first mode provides a fixed 2.2 V, the second mode provides selectable outputs (0.5 V, 1.1 V, 1.5 V, and 2.0 V) of an internal DAC, and the third mode allows an external input from the REF\_AIN pin to be used as the clamp reference. This REF\_AIN pin is bidirectional and also acts as an output of the internal DAC. Table 5 shows the relationship between the register and clamp level. Table 6 shows the DAC configuration.

(1) If the sensor signal is directly input to the AFE, the enternal capacitor should not be connected.

### Figure 7. V<sub>CLP</sub> Block Diagram

#### Table 5. Clamp Level Selection

| MODE SETTING<br>AINx_REF_SEL[1:0] <sup>(1)</sup> |                   | CLAMP LEVEL                                    |
|--|-------------------|--|
| 0  | 2.2 V             |  |
| 1  | V <sub>RINT</sub> | Reference DAC (0.5 V, 1.1 V, 1.5 V, and 2.0 V) |
| 2  | V <sub>REXT</sub> | REF_AIN external input                         |

(1) AINx\_CLP\_SEL (x = 1, 2, 3, and 4).

#### Table 6. V<sub>RINT</sub> Voltage Selection

| SETTING CODE VRINT_SEL | REF DAC V <sub>RINT</sub> (V) |
|------------------------|-------------------------------|
| 2                      | 0.5                           |
| 3                      | 1.1                           |
| 0                      | 1.5 (default)                 |
| 1                      | 2.0                           |

If line clamp mode is used, the CLPDM period should be configured by the internal registers. The CLPDM period is determined with reference to the line cycle signal for the sensor (LS). Thus, the start and end of CLPDM are each defined as the number of pixels from the LS falling edge. Because CLPDM is used as the clamp period, it should be assigned for the interval of any dummy or optical black pixels. Figure 8 shows the relationship between LS and CLPDM.

Figure 8. Line Clamp Period Setting

#### **Pixel Clamp Period Setting**

In pixel clamp mode, without CLPDM, the sensor signal is clamped with CLP\_A and CLP\_B pulses. CLP\_A corresponds to AIN1 and AIN2; CLP\_B corresponds to AIN3 and AIN4. The start of these pulses is synchronized with the SHP\_y rising edge (where y = A or B). There are two options to configure the end position: first, to automatically set the pulse width to 50% that of SHP\_y; and second, to manually configure the end position using an internal register. Figure 9 and Figure 10 illustrate the details of the clamp pulse function in automatic and manual modes, respectively.

## Automatic Mode (CLP\_TF\_AT\_DIS = 0)

Figure 9 shows the automatic mode when CLP\_TF\_AT\_DIS is '0'.

Figure 9. Automatic Mode

### Manual Mode (CLP\_TF\_AT\_DIS = 1)

Figure 10 shows the manual mode when CLP\_TF\_AT\_DIS is '1'.

Figure 10. Manual Mode

In pixel clamp mode when CLPDM is active, the sensor signal is clamped with SHP\_y. Therefore, the pixel clamp operation is closely related with the status of CLPDM. The condition of CLPDM should be properly defined with the internal registers. Because CLPDM is always high during a default condition after reset or power up, the status of CLPDM should be defined according to this sequence. Furthermore, the CLPDM status should be defined in the second step of the flowchart shown in Figure 11 for either configuration. All other user-dependent settings, except XLSYNC SEL and EN OUT of the software reset sequence, are described in Figure 11.

a) Only Pixel clamp

b) Line clamp + Pixel clamp

(1) Internal registers: AINx\_CLP\_SEL = addresses 16 and 17; LINT = address 7; DM\_STR = address 8; DM\_END = address 9; and EN\_CLPDM = address 399, bit 1.

#### Figure 11. Configuration Sequence for Pixel Clamp

VSP5610

VSP5611

VSP5612 SBES021 – JUNE 2011

The SH output can be amplified using programmable analog gain. This gain can be set from 0.5 V/V to 3.5 V/V with a step size of 3/64 V/V.

The gain setting can be controlled by an internal register (APG\_x). Equation 1 shows the relationship between the setting code and gain. The gain of each of the four channels can be set independently using different registers. Note that the black pixel level may possibly change as a result of the change in the gain; therefore, the appropriate timing of the gain change should be used to avoid degradation in image quality. Figure 12 shows analog gain as a function of gain control code in terms of V/V. Figure 13 shows the maximum allowed input signal as a function of gain control code.

## DIGITAL PROGRAMMABLE GAIN (DPG)

The VSP5610/11/12 provide a maximum digital gain of 2 V/V. The total gain is fixed by the combination of CDS/SH analog gain (APG) and digital gain (DPG). DPG is controlled by an 8-bit internal register (DPG\_x) that can set the gain from 1 V/V to 2 V/V, as defined by Equation 2. This register is included in each of the four channels, so the gain of each channel can be set independently.

Figure 14 shows the relationship between the digital gain and register code. Note that the default value is 1 V/V.

$$DPG (V/V) = \frac{1}{256} \times Code + 1 \qquad (Code = 0 LSB to 255 LSB)$$

# ADC

The ADC output format is selectable as twos complement or offset binary by configuring a register. Table 7 shows the relationship between register setting and condition.

| Table 7. ADC Data F | ormat Configuration |
|---------------------|---------------------|
|                     |                     |

| ADC_DAT_FRM | MODE            |
|-------------|-----------------|
| 0 (default) | Twos complement |
| 1           | Offset binary   |

# OFFSET DAC

The VSP5610/11/12 have an independent DAC in each channel for offset level correction of the input signal. The correction range is ±250 mV and resolution is 8 bits. The DAC output voltage can be set by register settings. Table 8 and Figure 15 show the relationship between the output and setting codes. The setting code is defined in twos complement format. The DAC output offset voltage in millivolts as a function of the register setting is given in Equation 3.

| SETTING CODE<br>OFDAC_x[7:0] <sup>(1)</sup> | OUTPUT (mV) |

(3)

### TIMING GENERATOR (TG)

The image sensor timing generator (TG) is incorporated into these devices. The TG provides six signals that function as slow transfer clocks and eight signals that function as fast transfer clocks. In addition, the fast clock signals can also be used as slow clock signals. The TG signals are synchronized with LS (which is the image sensor line cycle) and are completely controlled by the internal registers. Because the TG output is locked under the default setting, EN\_OUT (address 2, bit 10) should be set to '1' to enable the outputs.

### LINE SYNCHRONOUS FUNCTION

The VSP5610/11/12 have two modes for synchronizing the sensor line cycle: internal line (Figure 16) and external line syncronous mode (Figure 17). In internal line synchronous mode, the line cycle signal (LS) is generated after a certain number of MCLK cycles that are counted by an internal counter (PIX\_CNT). The number of MCLK cycles is determined by the LINT[19:0] register; the counter clears after LS is generated. The active LS period is equal to one MCLK cycle period.

Figure 17. External Line Synchronous Mode (XLSYNC\_SEL = 0, default)

|                      | PARAMETER                 | TEST CONDITION | MIN | ТҮР      | MAX                 | UNIT   |
|----------------------|---------------------------|----------------|-----|----------|---------------------|--------|
| t <sub>LINE</sub>    | Line cycle period setting | XLSYNC = 1     | 3   | LINT + 1 | 2 <sup>20</sup> – 1 | Clocks |
| t <sub>XLS_ACT</sub> | XLSYNC active period      | XLSYNC = 0     | 3   |          |                     | Clocks |
| t <sub>XLS_S</sub>   | XLSYNC setup to MCLK      | XLSYNC = 0     | 10  |          |                     | ns     |
| t <sub>XLS_H</sub>   | XLSYNC hold to MCLK       | XLSYNC = 0     | 10  |          |                     | ns     |

### Table 9. Timing Requirements for Figure 16 and Figure 17

The other mode is the external line synchronous mode which requires an external signal (XLSYNC). In this mode, if the logic circuit detects an active XLSYNC period for more than three MCLK cycles, the internal line synchronous signal (LS) is generated. This mode has a function that mask XLSYNC in order to avoid noise interference. The duration of the XLSYNC mask can be set by the LINT[19:0] register, which is also used in the internal line synchronous mode.

The two line synchronous modes and the polarity can be selected by the XLSYNC\_SEL and XLSYNC\_POL registers, respectively. The default settings are external mode and active high polarity. XLSYNC can be used to output some internal signals. Table 10 shows the register settings required to select the desired output signals.

PIX\_CNT can be automatically reset by LS\_CNT\_RST (which is an internal register). Before performing this function, a software reset must be executed in order set RST\_ALL to '1'. If LS\_CNT\_RST is set to '1' after a software reset, the pixel counter is then held at '0'. To make the counter active, LS\_CNT\_RST should return to '0'.

| REGISTER SETTING<br>XLSYNC_OUT | OUTPUT SIGNAL |
|--------------------------------|---------------|
| 0                              | LS            |
| 1                              | CLPDM         |
| 2                              | Reserved      |
| 3                              | Reserved      |

### Table 10. XLSYNC Output Signal (XLSYNC\_SEL = 1)

## SLOW TRANSFER CLOCK SETTING (XST, XSHn, XCLR)

XST, XSHn (where n = 1 to 4), and XCLR are slow transfer clocks that can be configured by setting the initial polarity and toggle points. As shown in Table 11, the predetermined number of toggle points is different for each signal. Because the two toggles generate one pulse, the number of pulses is half the number of toggles.

| SIGNAL | TOGGLE | PULSE |
|--------|--------|-------|
| XST    | 8      | 4     |
| XSHn   | 16     | 8     |
| XCLR   | 48     | 24    |

#### Table 11. Toggle Number and Generated Pulse

VSP5610 VSP5611 VSP5612 SBES021 – JUNE 2011

www.ti.com

Each toggle position is defined by a register that is exclusive for each signal. The toggle position is synchronized with LS and the gap between the toggle position and the LS falling edge. The LS falling edge is defined in terms of  $t_{MCLK}$ , the cycle period of MCLK. This gap is set by register settings and is defined by Equation 4:

 $t = (Xn_T(k) + 1) \times t_{MCLK}$ 

where:

- n = ST, SHn, CLR
- k = 0 to 7 (XST); k = 0 to 15 (XSHn); k = 0 to 47 (XCLR)

Xn\_T(k) is less than LINT and is the register value of the toggle setting

(4)

The toggle for each signal can be disabled with register settings. To make the toggle active, Xn\_TGL\_EN should be set to '1'. However, because XST shares a pin with GPIO3, pin function should be configured with the GPIO3\_XST\_SEL register. Figure 18 shows the configuration regarding the slow transfer clock.

(1) If Xn\_Tn is set to '0', the toggle position is ignored (except for Xn\_T0).

(2) The period between the toggle position and LS falling edge =  $(Xn_T(k) + 1) \times t_{MCLK}$ .

- (3) The following requirement must be satisfied:  $Xn_T(k) < Xn_T(k + 1)$ .
- (4) The signal is set to the desired polarity settings at the falling edge of LS.

## FAST TRANSFER CLOCK PULSE SETTING

XP1/2, X1L, X2L, XRS, XCP, and XP3/4 are fast transfer clock signals with rising and falling edges that are configurable via register settings. Figure 19 shows the block diagram of the fast clock configuration. In Figure 19, the *DLL Tap Selector* is used to select both the rising and the falling edges of each signal from among 48 tap positions.

The XP2 clock signal is an inverse of XP1 and shares rising and falling edge settings. Similarly, XP4 is an inverse of XP3 and likewise shares rising and falling edge settings. The other signals have individual configuration registers for setting the position of both edges.

In addition, it is possible to change the clock rate of each signal with register settings. The clock rate is based on the frequency of MCLK. XP1 and XP2 can select x1, x2, or x4 modes with common settings. XP3 and XP4 can also select x1, x2, or x4 modes with common settings. The other signals can choose between the x1 and x2 rate settings.

Note that two independent sets of registers are available to set the clock rate, the clock rising edge, and the clock falling edge for operation in x1-mode and x2-mode.

### Fast Transfer Clock Pulse Timing

This section describes the timing of the fast transfer clock pulse for XRS (Figure 20), XCP (Figure 21), XP1 and XP2 (Figure 22), XP3 and XP4 (Figure 23), and X1L and X2L (Figure 24).

# Table 16. Timing Requirements for Figure 24

## SERIAL INTERFACE

All device functions and settings are controlled through the serial interface. The serial interface consists of three signals (SCLK, SEN, and SDI) for register writing, and a fourth signal (SDO) for readback. SDO shares the terminal with the GPIO signal; thus, a register setting is required to activate the SDO function. Other signals are assigned to individual terminals.

Serial data are composed of 30 bits total, as shown in Figure 25. 10 bits are assigned for the register address and 20 bits for register data. The input serial data at SDI are sequentially stored in a shift register at the SCLK rising edge. Data shift operation is performed at the SCLK rising edges with SEN low. All 30 input data bits are loaded to a parallel latch in an internal register at the rising edge of SEN.

This device has two modes: read and write. The mode selection can be made via the SPL\_RW internal register, located at bit 0 of address 0. SPL\_RW = 0 implies a write mode and SPL\_RW = 1 implies read mode.

|           | 10- | Bit Addr | ess |    | 20-Bit Data |     |  |    |    |

| MSB ← LSB |     |          |     |    |             |     |  |    |    |

Figure 25. Serial I/F Data Format

# WRITE MODE (SPI\_RW = 0, Default)

Normally, one serial interface command is sent by one address and data combination. The address should be sent MSB first. Data are stored into the respective register, as indicated by the address. If the serial data at the end of the data stream are less than 30 bits, the last incomplete serial data are discarded. Figure 26 shows the SPI signal flow while in write mode.

Figure 26. SPI Signal Flow of Write Mode

ASIC/CPU

### READ MODE (SPI\_RW = 1)

In read mode, two types of connections are possible between the AFE and external systems such as an ASIC or CPU. One connection is the four-wire connection in which the SDI and SDO pins are separately connected to the system as shown in Figure 27a.

The other connection is a three-wire connection in which only the SDI pin is connected to the bidirectional I/O port of the external system, as shown in Figure 27b. In this case, SDI\_BUFF\_CTRL should be set to '1' to create an SPI bidirectional port. The bit flow of the four-wire connection is shown in Figure 28. The bit flow of the three-wire connection is shown in Figure 29. As shown in Figure 29, SDI changes from an input to an output at the SCLK falling edge after the end of the A[9:0] input. Because the SDI port is always in pull down mode, the external pull down resistance is unnecessary.

Device

a) Four-Wire Connection SDI Input Port: SDI\_BUFF\_CTRL = 0 b) Three-Wire Connection SDI Bidirectional Port: SDI\_BUFF\_CTRL = 1

<sup>(1)</sup> The marketing status values are defined as follows:

ACTIVE: Product device recommended for new designs.

LIFEBUY: TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

NRND: Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

PREVIEW: Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

(2) Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check http://www.ti.com/productcontent for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes. **Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between

the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

Green (RoHS & no Sb/Br): TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. -- The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

Important Information and Disclaimer: The information provided on this page represents TI's knowledge and belief as of the date that it is provided. TI bases its knowledge and belief on information provided by third parties, and makes no representation or warranty as to the accuracy of such information. Efforts are underway to better integrate information from third parties. TI has taken and continues to take reasonable steps to provide representative and accurate information but may not have conducted destructive testing or chemical analysis on incoming materials and chemicals. TI and TI suppliers consider certain information to be proprietary, and thus CAS numbers and other limited information may not be available for release.

In no event shall TI's liability arising out of such information exceed the total purchase price of the TI part(s) at issue in this document sold by TI to Customer on an annual basis.

NOTES: A. All linear dimensions are in millimeters. Dimensioning and tolerancing per ASME Y14.5M-1994.

- B. This drawing is subject to change without notice.
- C. Quad Flatpack, No-leads (QFN) package configuration.
- D. The package thermal pad must be soldered to the board for thermal and mechanical performance.
- E. See the additional figure in the Product Data Sheet for details regarding the exposed thermal pad features and dimensions.

# RSH (S-PVQFN-N56)

# PLASTIC QUAD FLATPACK NO-LEAD

### THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at www.ti.com.

The exposed thermal pad dimensions for this package are shown in the following illustration.

NOTE: All linear dimensions are in millimeters

RSH (S-PVQFN-N56)

PLASTIC QUAD FLATPACK NO-LEAD

NOTES: A. All linear dimensions are in millimeters.

- B. This drawing is subject to change without notice.
- C. Publication IPC-7351 is recommended for alternate designs.
- D. This package is designed to be soldered to a thermal pad on the board. Refer to Application Note, Quad Flat-Pack Packages, Texas Instruments Literature No. SLUA271, and also the Product Data Sheets for specific thermal information, via requirements, and recommended board layout. These documents are available at www.ti.com <http://www.ti.com>.
- E. Laser cutting apertures with trapezoidal walls and also rounding corners will offer better paste release. Customers should contact their board assembly site for stencil design recommendations. Refer to IPC 7525 for stencil design considerations.
- F. Customers should contact their board fabrication site for recommended solder mask tolerances and via tenting recommendations for vias placed in the thermal pad.

#### **IMPORTANT NOTICE**

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of TI information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation. Information of third parties may be subject to additional restrictions.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.

TI products are not authorized for use in safety-critical applications (such as life support) where a failure of the TI product would reasonably be expected to cause severe personal injury or death, unless officers of the parties have executed an agreement specifically governing such use. Buyers represent that they have all necessary expertise in the safety and regulatory ramifications of their applications, and acknowledge and agree that they are solely responsible for all legal, regulatory and safety-related requirements concerning their products and any use of TI products in such safety-critical applications, notwithstanding any applications-related information or support that may be provided by TI. Further, Buyers must fully indemnify TI and its representatives against any damages arising out of the use of TI products in such safety-critical applications.

TI products are neither designed nor intended for use in military/aerospace applications or environments unless the TI products are specifically designated by TI as military-grade or "enhanced plastic." Only products designated by TI as military-grade meet military specifications. Buyers acknowledge and agree that any such use of TI products which TI has not designated as military-grade is solely at the Buyer's risk, and that they are solely responsible for compliance with all legal and regulatory requirements in connection with such use.

TI products are neither designed nor intended for use in automotive applications or environments unless the specific TI products are designated by TI as compliant with ISO/TS 16949 requirements. Buyers acknowledge and agree that, if they use any non-designated products in automotive applications, TI will not be responsible for any failure to meet such requirements.
